Thunderstorms with high rainfall intensities and damaging winds are common during the spring and summer months. Heavy fog, reducing prevailing visibility to ½-mile (0.4 km) or less, occurs an average of 18 days a year. The prevailing wind direction is to the south with an average velocity of less than 10 miles (16 km) per hour (MWH 2002). The total annual precipitation is approximately 42 to 44 inches (in.) [107 to 112 centimeters (cm)], with nearly 50% occurring during the growing season from May to October. Precipitation is greater than or equal to 0.5 in. (1.3 cm) approximately 28 days per year. Table 2-2 presents climatological data for southern Indiana.

There are four weather stations located in Jefferson County, three of which are active (COOP ID 122184 and 125237 and WBAN 53814). These stations collect limited data (e.g., minimum/maximum temperature, precipitation, etc.) that may be accessed from the National Climatic Data Center (NCDC) [see http://www.ncdc.noaa.gov/]. Information on wind speed and direction at all heights is not available in this region. The closest location where related data are collected is Wilmington, Ohio [National Weather Service (NWS) 2002]. Wind speed and direction data may be obtained from Indianapolis, Indiana, and Louisville, Kentucky. Data for the 30-year period ending in 1990 from the Louisville International Airport are provided in Table 2-3 (NWS 2002). These values are consistent with those reported in MWH (2002).

Air monitoring stations are located at six locations in Jefferson County (Wilson Road, Bacon Ridge Road, K Road, Graham Road, Kent Hall-State Hospital, and Sunrise Golf course), which at various points in time were used to monitor for total suspended particulates, sulfur dioxide, nitrogen dioxide, and/or nitrous oxides. The Wilson Road station was the only active station in 2001, which monitored sulfur dioxide. This information is based on EPA's air pollution database, AIRS.

The JPG region also is subject to tornadoes, which are most common in southeastern Indiana from May through July. A tornado occurred at JPG in 1998. The tornado path traversed the area north of the firing line, entering the installation north of F Road and exiting the installation at approximately H Road (see Figure 1-1). If the tornado followed a straight path, it would have touched down approximately 2.5 miles (4 km) north of the DU Impact Area. According to the NCDC, for the period from 1950 to 1995, an annual average of 20 tornadoes per year occurred in the State of Indiana. The annual average number of strong—violent tornadoes (F2–F5 on the Fujita scale) in Indiana is 7 (NCDC 2001).

The State of Indiana's ambient air quality standards are identical to the National Ambient Air Quality Standards. Air quality monitoring is conducted under the IDEM's Office of Air Management. JPG is located in a region that complies with both State of Indiana and Federal ambient air quality standards (IDEM 2001). During operation, JPG was not classified as a major source contributor to air pollution (U.S. Army 1995b). No emission sources are associated with the DU Impact Area.

2.5 GEOLOGY, SOILS, AND SEISMOLOGY

Information on JPG's bedrock and glacial geology, soils, and seismology are provided in Sections 2.5.1, 2.5.2, and 2.5.3, respectively.

2.5.1 Bedrock and Glacial Geology

JPG is located on the western flank of the Cincinnati Arch, a broad structural feature that separates the Illinois and Appalachian Basins (Figure 2-3). Most of the installation is covered by a layer of Pleistocene glacial deposits that overlies Paleozoic bedrock. These deposits average about 25 ft (7.6 m) in thickness, and range in thickness from 3.5 to 45 ft (1.1 to 13.7 m) [Figure 2-4]. The underlying bedrock consists of interbedded limestone, dolomite, and shale. The bedrock thickness encountered in wells drilled south of

the firing line has varied from approximately 10 to 65 ft (3 to 20 m) [MWH 2002]. The thickness of the underlying bedrock formations is variable, as shown on the cross-section of the cantonment area in Figure 2-5, reflecting the installation's location on the Cincinnati Arch. For example, the Louisville Limestone has a thickness of approximately 50 ft (15.2 m) on the western edge of the installation but pinches out to the east (Figure 2-5) [MWH 2002].

Within the DU Impact Area, the depth to bedrock ranges from 2 to more than 19 ft (0.6 to more than 5.8 m) based on the stratigraphy in the groundwater monitoring wells in this area. The bedrock in this area is described as fine-grained, light-to-medium gray limestone with shale streaks.

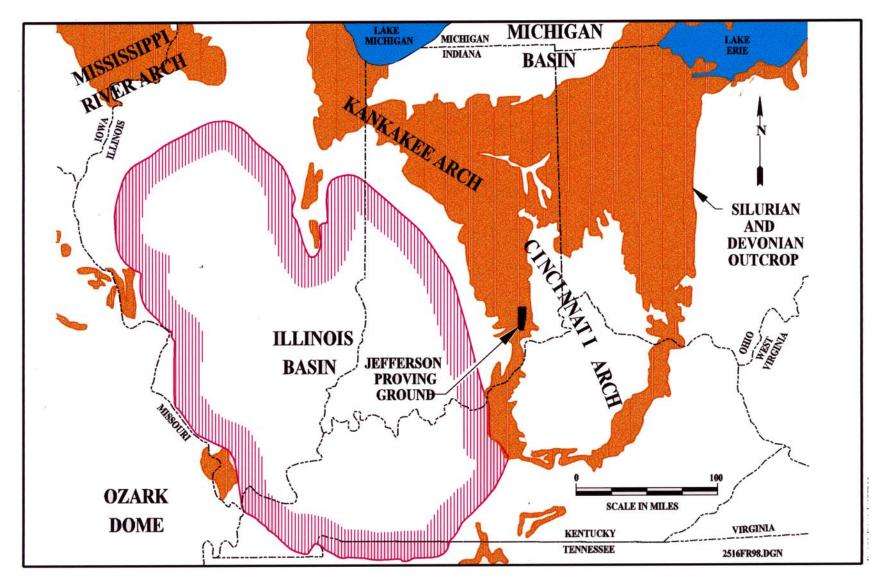

The overlying glacial deposits south of the firing line consist of interbedded silts and clays, and silts with gravel, based on a review of borehole logs from wells drilled on the installation. Closer to the bedrock contact, the glacial deposits contain chert, dolomite, and limestone rock fragments overlain by silt and clay layers that contain discontinuous gravel lenses (MWH 2002).

Within the DU Impact Area, the glacial deposits are described as brown, silty clay containing some black gravel/rock fragments and some chalky white rock fragments. From the ground surface to a depth of 1 to 1.5 ft (0.3 to 0.5 m) below ground surface (BGS) has been disturbed from detonation.

2.5.2 Soils

Soils at JPG developed from glacially derived parent material. There are two major soil associations present on the installation: Cobbsfork-Avonburg and Cincinnati-Rossmoyne Hickory (Figure 2-6). The Cobbsfork-Avonburg soils are present on upland glacial drift plains characterized by smooth topography with slopes ranging from 0 to 4%. The nearly level Cobbsfork soils have a seasonal high water table and are located on tabular divides. Typically, these soils have surface and subsurface layers composed of grayish-brown silt loam; both layers are about 6 in. (0.15 m) thick. The Avonburg soils also have a seasonal high water table and are located in relatively broad tabular divides and upper back slopes. These soils have a low-permeability fragipan in the subsoil. These soils have a brown silt loam surface layer about 10 in. (0.25 m) thick (MWH 2002).

^aTo convert from miles/hour to km/hour, multiply by 1.61.

Figure 2-3. Regional Structural Setting of Jefferson Proving Ground

	9	Jefferson	Proving Ground Stratigraphic Colum	n (South of the Firing Line)		
	CEN		Stratigraphic Unit	Hydrogeologic Characteristics		
	PLEISTOCENE	0.00	GLACIAL DEPOSITS (3.5-45ft.) Mostly silt and clay with minor sand and gravel (see glacial deposit lithologic column - (Figure)	Poor aquifer, minor sand and gravel lenses are discontinuous and often have fines		
			NORTH VERNON LIMESTONE (>12ft.) Limestone, medium gray to blue gray, crinoids common, some stromatoparoids, skeletal grainstone beds, mostly low porosity	Generally poor aquifer due to low porosity and few fractures. Weathered styolite zones yield some water		
	DEVONIAN		JEFFERSONVILLE LIMESTONE (± 21ft) Limestone, light brown to tan, corals and stromatoparoids abundant in lower horizons, brachiopods in upper part, some cross-bedding, some skeletal grainstone beds,minor weathered chert nodules, orange weathered color near top of bedrock, especially along stylolites, mostly low porosity	Generally poor aquifer due to low porosity and few fractures. Weathered styolite zones underlying glacial cover yield some water		
			GENEVA DOLOMITE (11-12ft.) Dolomite, buff to medium brown, few tan minor wispy shale laminae, large calcite crystal inclusions common	Poor aquifer. Very low porosity. Minor fracturin		
			LOUISVILLE LIMESTONE (0-43ft.) Dolomitic limestone and dolomite, tan to light gray, mostly non-fossiliferous except for crinoid zone in lower part, brachiopods abundant and crinoids common in MW93-7, some chert zones, mottling and irregular banding common	Highly variable water yielding characteristics. Mostly low porosity, but vuggy porosity common to very abundant, fracturing common in porous zones		
	SILURIAN					
			WALDRON SHALE (4-12ft.) Shale, olive gray to dark greenish gray, mostly few to no fossils, but locally abundant crinoids	Only confining unit within ± 150ft of carbonate strata		
			LAUREL MEMBER (SALAMONIE DOL.) (25-45 ft.) Dolomite and dolomitic limestone, light gray to tan, few fossils in upper part, brachiopods and crinoids common in lower part, chert nodules abundant in upper part, vuggy porosity well developed in fossiliferous lower part (MW93-7)	Highly variable water yielding characteristics. High yielding wells (e.g.,Red Lead and Yellow Sulfur area) probably near fracture zones. Porosity generally low but well developed in fossiliferous zone in lower part (MW93-7)		
20ft.			OSGOOD MEMBER (SALAMONIE DOL.) Shale, medium to dark gray, no fossil, calcareous, some dolomite and siltstone interbeds, minor pyrite crystals	Confining Unit		
1		LCITE CRYSTALS @ -CHERT NODULE				
				⊚ -CRINOID		
			NOT TO SCALE -STROMAT	OPAROIDS -BRACHIOPOD
